

Objectives for today

- Identify various ways of writing and running Python code
- Learn basics of Python syntax
- Define three types of variables: integers, floats, and strings
- Concatenate & slice strings
- Determine rules for variable names

There are multiple ways to interact with the Python interpreter

- Command line (terminal)
 - Line-by-line coding
 - Running "Scripts"

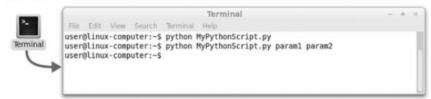

"Terminal" comes from the days before desktop computers, when a computer occupied a set of cabinets or even an entire room. A terminal was a device with a (text-only) monitor and keyboard whereby a user could control the computer from a distance over a dedicated, wired connection.

A DEC VT100 terminal at the Living Computer Museum (apparently connected to the museum's DEC PDP-11/70

mainframe computer). Source: Wikipedia

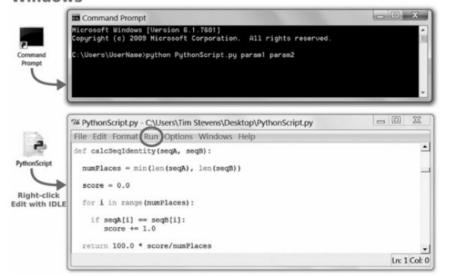

Linux

Macintosh

Windows

Running a Python script from different operating systems

(from http://www.cambridge.org/pythonforbiology)

If you have a Mac

code!

- Macs ship with Python already installed.
- You can check which version by opening **Terminal** & typing
 python --version
 - For this course, we'll be using Python 3.7 (or above).

```

Last login: Thu Sep 26 09:22:42 on ttys000

[(base) $ python

Python 3.7.3 (default, Mar 27 2019, 16:54:48)

[Clang 4.0.1 (tags/RELEASE_401/final)] :: Anaconda, Inc. on darwin

Type "help", "copyright", "credits" or "license" for more information.

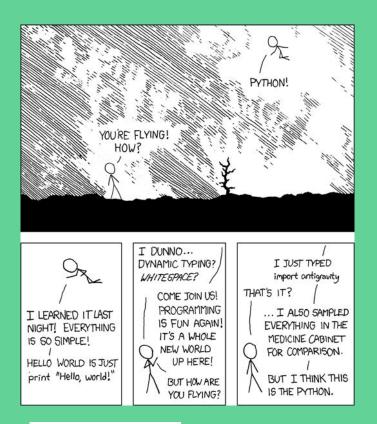

>>>

The ">>>" tells you you're inside the Python
```

prompt, and the computer is ready for some

Let's see if Python can make us fly...?

import antigravity

https://xkcd.com/353/

Code: https://github.com/python/cpython/blob/main/Lib/antigravity.py#L7-L17

Explanation: https://martinapugliese.github.io/tech/python-antigravity/

Useful Linux Commands

In Jupyter
Notebook, add a
! in front to use
these. E.g., !pwd

Command	Description
pwd	Print working directory
ls	List contents
cd	Change directory
ср	Copy files from the current directory to a different directory
mv	Move or rename files
mkdir	Make a directory
touch	Create a blank file

More details: https://www.hostinger.com/tutorials/linux-commands
https://jakevdp.github.io/PythonDataScienceHandbook/01.05-ipython-and-shell-commands.html

There are multiple ways to interact with the Python interpreter

- Command line
 - Line-by-line coding
 - Running "Scripts"
- Integrated Development Environments
 - Folks have strong opinions about these, and each have pros/cons.
 - A few good options are:
 - Visual Code (https://code.visualstudio.com/download)
 - Spyder (Included with Anaconda)
- Jupyter Notebook most of what we'll do in this course

Integrated Development Environments (IDEs)

- Help you write, debug, and compile code
 - Compiling is the process of translating your source code into machine code
- Useful because they have features like line numbers and syntax highlighting, which colors your code based on the syntax.
- Often have auto-completion, memory for commands, and provide information about functions

Anaconda is an open-source distribution of Python, focused on scientific computing in Python.

Includes:

- "Conda," a package management tool
- Useful code packages
- A couple applications for editing & running code:
 - Spyder (Python IDE)
 - Jupyter Notebooks

A few notes

Macs have a native installation of Python.

- It may be older & will not include the extra packages that you will need for this class, and is best left untouched.
- Downloading Anaconda will install a separate, independent install of Python, leaving your native install untouched.

Windows does not require Python natively and so it is not typically pre-installed.

If you're not sure which Python your computer is using, ask it (in Python):

>>> which python

Objectives for today

- Identify various ways of writing and running Python code
- Learn basics of Python syntax
- Define three types of variables: integers, floats, and strings
- Concatenate & slice strings
- Determine rules for variable names

There are different types of programming languages, each with their own syntax, or rules.

- **Syntax**: the rules of a programming language
 - Includes punctuation, spacing, indentation, etc.
- Each language has strengths & weaknesses.
- Regardless, each language ultimately needs to communicate with the hardware of the computer, in 1's and 0's.
 - It's similar to DNA! And similar to DNA, we don't often describe it in individual base pairs. Instead we describe genes and describe DNA in a higher level way.

Storing values

We can store values in variables, e.g.:

Variables can be text, integers, or floats (with decimals), e.g.:

Storing values

We can store values in variables, e.g.:

variable
$$1 = 48$$

We use an equal sign to assign the value to a name, but it's not the same thing as saying they are equal.

In other words, we're storing that value in the variable. (Think of them like cookie jars)

Creating new variables

- Names are always on the left of the `=`, values are always on the right
- Pick names that describe the data / value that they store
- Make variable names as descriptive and concise as possible (this is an art!)
- Variables cannot be Python keywords:

```
|>>> import keyword
|>>> print(keyword.kwlist)
['False', 'None', 'True', 'and', 'as', 'assert', 'async', 'await', 'break', 'class', 'continue', 'def',
  'del', 'elif', 'else', 'except', 'finally', 'for', 'from', 'global', 'if', 'import', 'in', 'is', 'lamb
  da', 'nonlocal', 'not', 'or', 'pass', 'raise', 'return', 'try', 'while', 'with', 'yield']
>>> |
```

(There are other rules for variable names....)

Python has many variable types, and each function a little bit differently.

Understanding your variable type is crucial for working with it.

Built-in simple variable types in Python

Туре	Example	Description
int	x = 1	integers (i.e., whole numbers)
float	x = 1.0	floating-point numbers (i.e., real numbers)
complex	x = 1 + 2j	Complex numbers (i.e., numbers with real and imaginary part)
bool	x = True	Boolean: True/False values
str	x = 'abc'	String: characters or text
NoneType	x = None	Special object indicating nulls

Integers, strings, floats

function to convert to integer

- Integers (int): any whole number
- Float (float): any number with a decimal point (floating point number)
- String (str): letters, numbers, symbols, spaces
 - Represented by matching beginning & ending quotes
 - Quotes can be single or double; use single within double
 - Use \ to ignore single quote
 - Concatenate strings with +

Checking variable types

This is a very useful troubleshooting step!

- You can check what type your variable (a) is by using type (a)
 - Alternatively, we can use:

```
>>> type(a) is float
or
>>> isinstance(x,float)
```

- Python lets you change the type of variables, however, you cannot combine types.
- Use del to delete variables

It's important to know the precision of your variables.

In most datasets, we are working with floats.

Autopsy Report:

Dr. Andrew Esty
Time of Death: 03/16 11:53
Cause of Death: Rounding Errors

Use print() often!

Original tweet

Historical sidenote

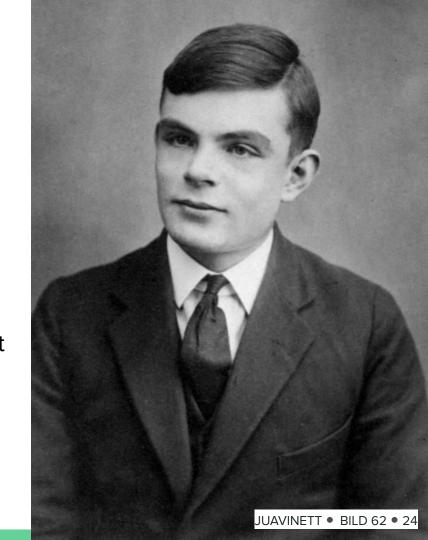

- A cipher is a procedure for encoding and decoding messages or data.
- By manipulating strings, it's quite straightforward to create an encoder using a few lines of code.
- During WWII, Germany used a variable encoder which changes its encoding strategy each time it runs.

Historical sidenote

- A team led by Alan Turing built & programmed machines that could crack the ENIGMA code, ultimately shortening the war & saving many lives.
- Alan Turing went on to make many contributions to computer science until he was prosecuted by the British Government for "homosexual activity"

Note: The Imitation Game is an Oscar-worthy depiction of his life and work (but takes some dramatic liberties...)

Let's get into a Jupyter notebook! Use the <u>magic link</u> to sync up your DataHub with our folder, and open notebook 02.

You'll also need to open the quiz on Canvas.
